Signs of Literacy Kaggle Research Competition, Nov 2018 – Jan 2019

Google owned Kaggle has selected us as one of a small number of pro bono competitions they support each year on the merits of our proposal, and the potential impact on the research field and community of the competition.

Kaggle will cover the running costs of the competition. We will provide the prize pool, and are now seeking to raise US \$30,000 from potential sponsors and partners.

The Proof of Concept will contain two parts:

- (1) Algorithmic identification of marks, initials and signatures.
- (2) Algorithmic discrimination between degrees of "sophistication" within the three categories of "mark"; "initial(s)", and "signature".

Having proven the concept, we will seek out an image or vision oriented computational laboratory with which to develop a grant funded collaboration to take the work further in 2019 and beyond.

Technical vision & role of the Kaggle competition

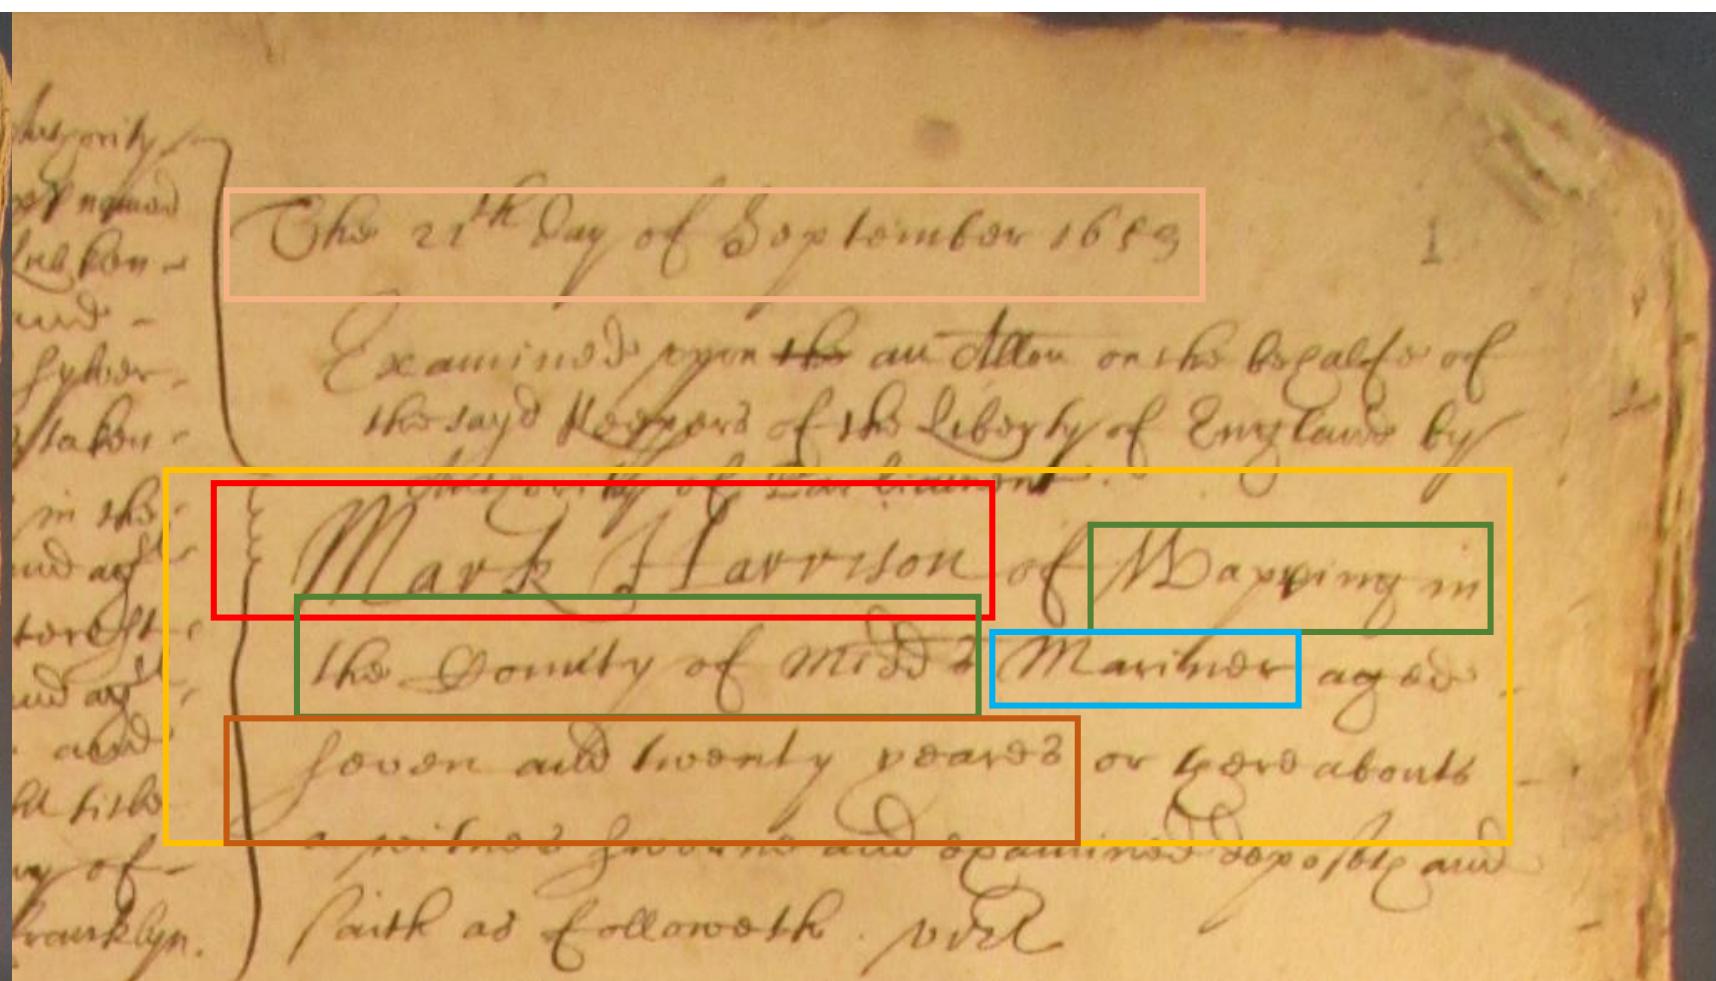

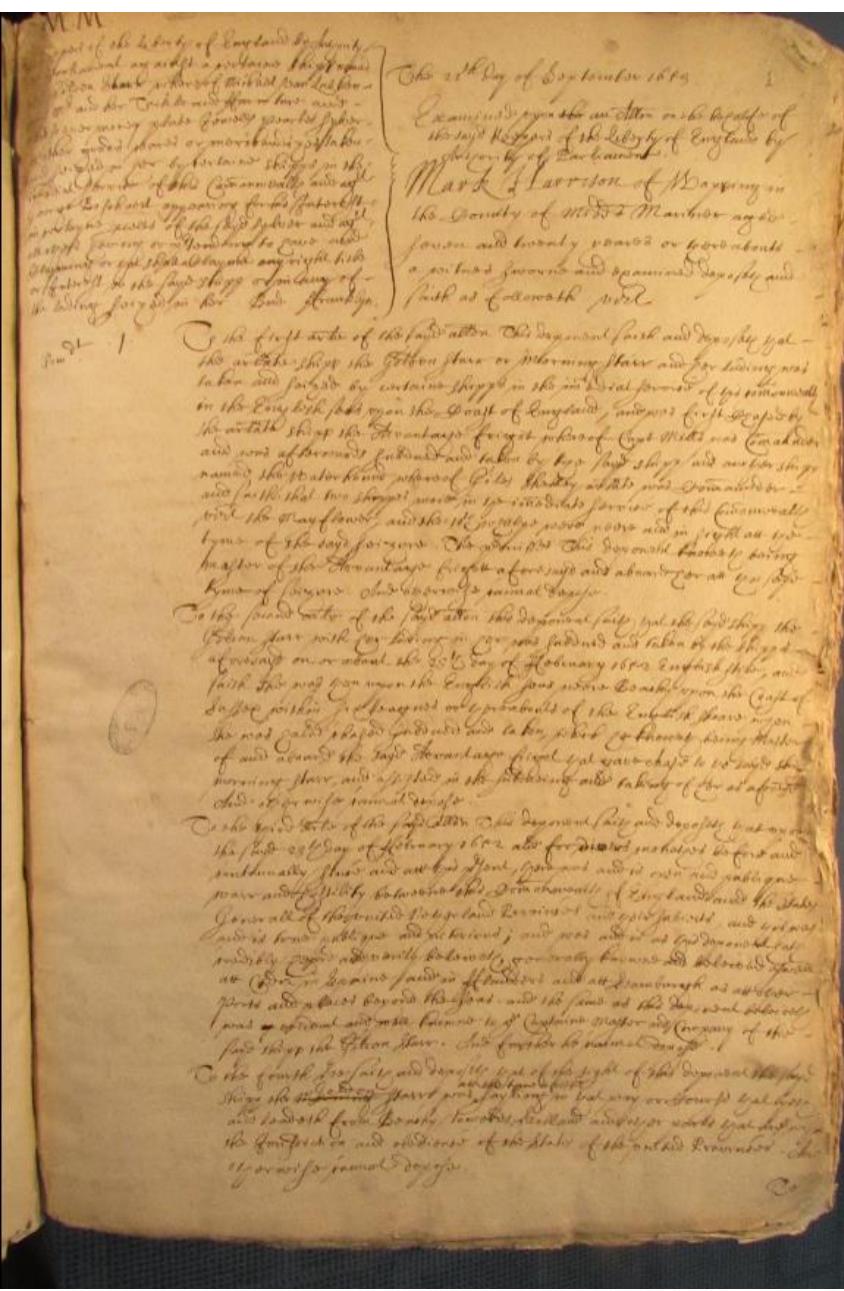

- Automatic identification of manuscript pages containing signoffs
- Markup of manuscript pages to isolate signoffs (marks, initials, signatures)
 - Hand markup of manuscript pages, but ideally automated markup
 - Signoffs can be single or multiple, for single or multiple depositions
 - Deponent signoffs; interpreter signoffs
- Automatic differentiation between classes of marks, initials and signatures
- Automatic differentiation within each class as to sophistication of execution & other parameters as a surrogate for literacy
- Automatic identification of manuscript pages containing deponent metadata (name; age; occupation; place of residence; date of deposition)
- Markup of manuscript pages to isolate deponent metadata
- Hand writing text recognition of deponent metadata and associate metadata with correct signoff

Legal deposition

Deposition of Mark Harrison; mariner and master; resident in Wapping, Middlesex; age 27;
Dated September 21st 1659 (TNA, HCA 13/68, ff. 1r-3r)

Metadata

20th Day of September 1603.

Porters handling coals, whale oil, ginger & corn

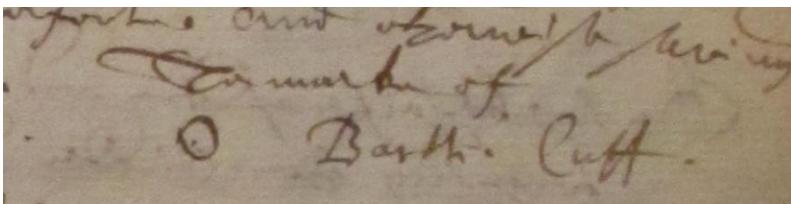

Richard Wincles, thirty-three year old porter, of the parish of Stepney, Middlesex, Dec. 15, 1656; employed as a labourer with fifteen other men to unload coals from the *Imployment* moored near Execution Dock, Wapping, into lighters for fixed rate of 12 s per man ([HCA 13/70 f.554r](#))

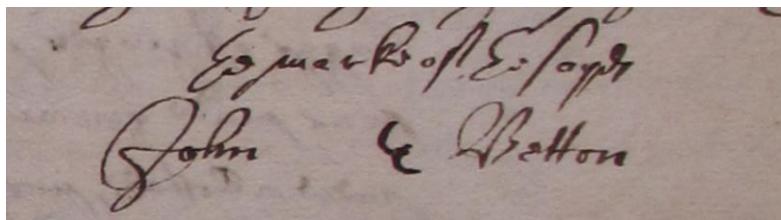

Edward Cranford, forty-four year old coale heaver or porter, of the parish of Stepney, Middlesex, Dec. 15, 1656; employed as a labourer with fifteen other men to unload coals from the *Imployment* moored near Execution Dock, Wapping, into lighters for fixed rate of 12 s per man ([HCA 13/70 f.555v](#))

Bartholomew Cuff, sixty year old porter of the Stillyard, of the parish of Allhallows the Greate, London, May 15, 1658; assisted in the landing of whale oil from lighters at the Stillyard Key and loading them away into a warehouse ([HCA 13/70 f.555v](#))

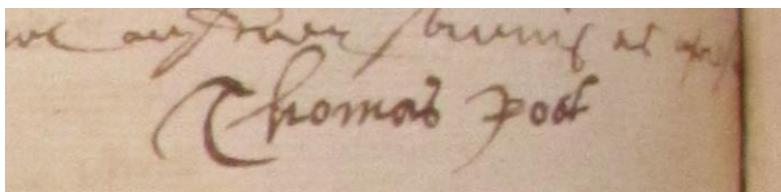

John Betton, fifty-four year old citizen and white baker of London, of the parish of Saint Buttolph Algate, London, Jul. 31, 1655; self-described as a porter employed by the Commissioners for Prize Goods to deliver ginger from a warehouse at Ralphes Key ([HCA 13/70 f.449r](#))

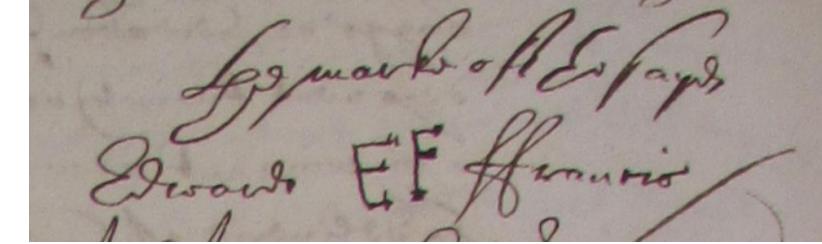

Edward Sherwin, fifty-six year old cittien and leatherseller, of the parish of Little Allhallowes, London, Jul. 31, 1655; self-described as a porter employed by the Commissioners for Prize Goods to deliver ginger from a warehouse at Ralphes Key ([HCA 13/70 f.449v](#))

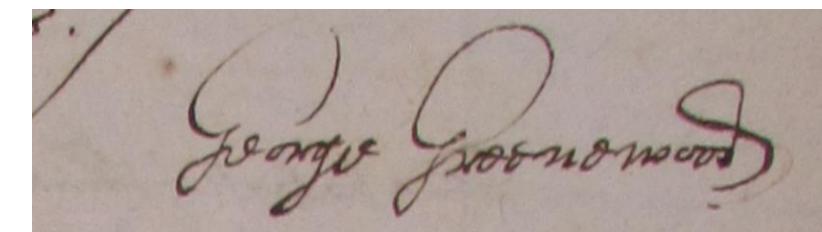

Thomas Roots, twenty-nine year old porter, of the parish of Greate Allhallowes, London, May 15, 1658; assisted in the landing of whale oil from lighters at the Stillyard Key, as one of the Stillyard porters, and loading them away into a warehouse ([HCA 13/72 f.330v](#))

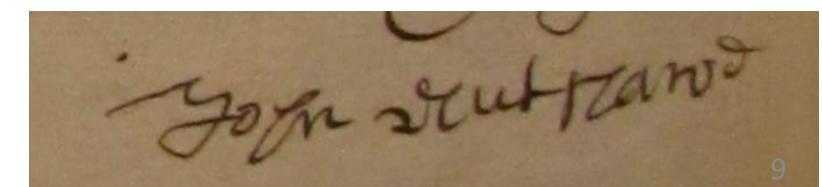

Edward ffrancis, citizen and merchant taylor of London, of the parish of Saint Olave in Southwarke, Jul. 31, 1655; self-described as a porter employed by the Commissioners for Prize Goods to deliver ginger from a warehouse at Ralphes Key ([HCA 13/70 f.450v](#))

George Greenwood, thirty year old citizen and vintner of London, of the parish of Saint Buttolph Bishopsgate, London, Jul. 31, 1655; self-described as a porter employed by the Commissioners for Prize Goods to deliver ginger from a warehouse at Ralphes Key ([HCA 13/70 f.454r](#))

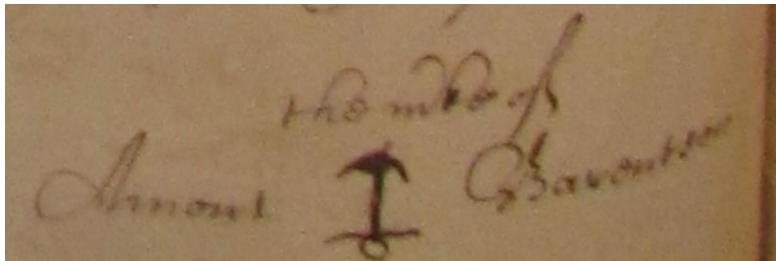

John Nutshall, fifty-five year old corne porter, of the parish of Saint Saviours Southwarke, Nov. 19, 1653; employed with a barber chyrurgeon/corne meter, an additional corne-meter, and other labourers to unlade a cargo of what in the *ffortune* of Stettin, moored against Limehouse; eight years of experience as a corne porter ([HCA 13/70 f.352v](#))

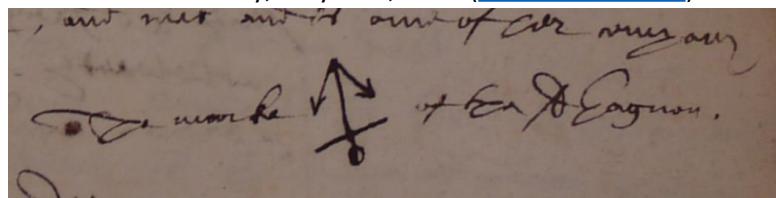

Anchors

Amons Barentsen, thirty-five year old mariner, of Copenhagen, Denmark, October 13th, 1653; self-described as an "ordinary mariner", hired to sail from the Sound to Hamburg on the *Golden Hawke* of Stockholm ([HCA 13/68 f.81v](#))

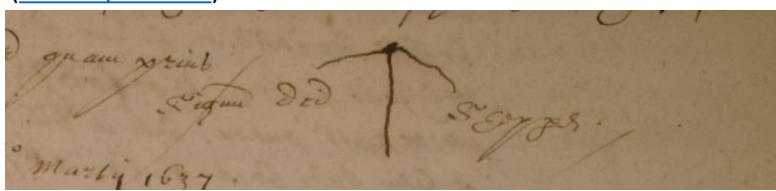

Claude de Gagnon, twenty-five year old mariner, of Melon, near Brest in Britanny, May 22nd, 1656 ([HCA 13/71 f.225r](#))

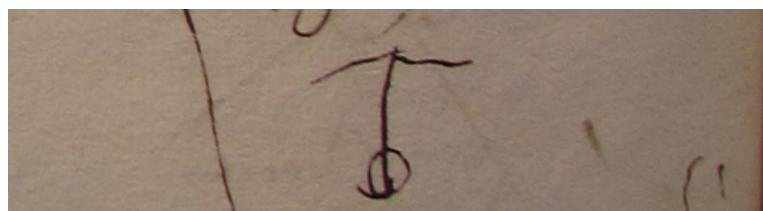

John Tylor, forty-two year old shipwright, of Lower Shadwell, in the parish of Stepney, Middlesex, February 14th, 1659 ([HCA 13/73 f.36r](#))

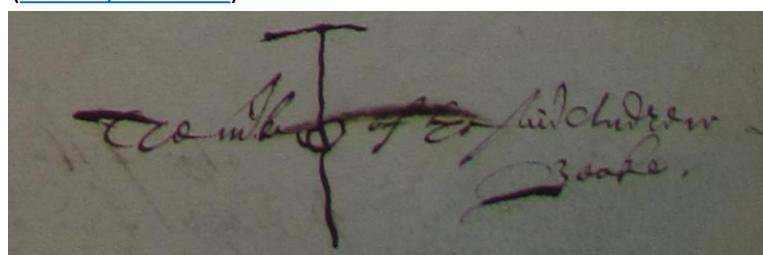

Richard Shepperd, fifty-eight year old cooke, of Brixton, Devon, March 29th, 1637; self-described cooke of the *Hope of Ipswich* ([HCA 13/53 f.87r](#))

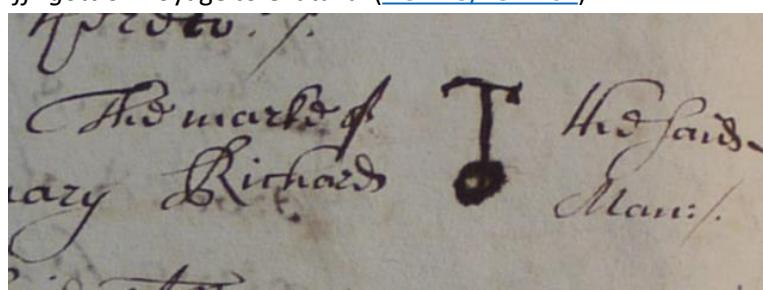

Andrew Beake, thirty-six year old lookeinglassemaker and formerly seaman, of Rose alley without Bishopsgate, London, January 21st, 1655 ([HCA 13/70 f.252v](#))

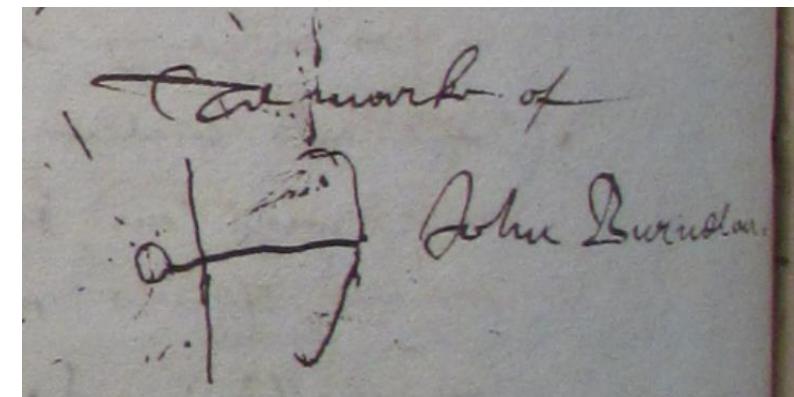

Andrew Beake, thirty-six year old looking-glasse maker, of Rose-Alley in Bishopsgate streete, London, February 13th, 1655 ([HCA 13/70 f.252v](#))

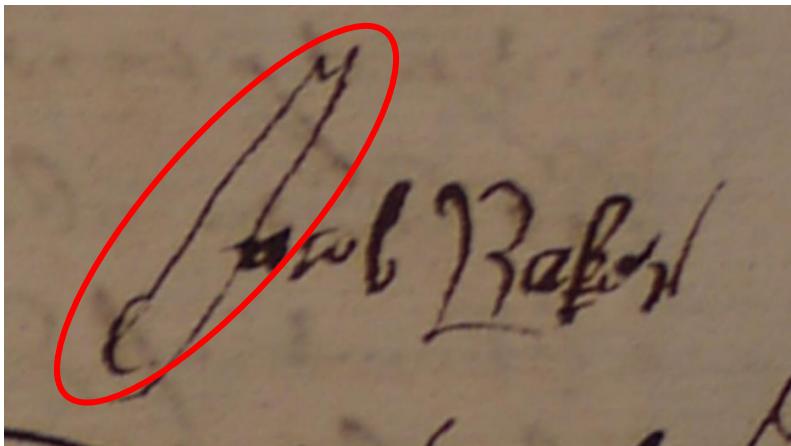

Richard Man, thirty-one year old mariner, of Southampton, January 8th, 1659; self-described common man of the *Lisbone ffrigott* on voyage to Oratava ([HCA 13/73 f.26v](#))

John Burnelau, twenty-eight year old sailor, of Mornar, France, March 30th, 1661 ([HCA 13/73 f.486v](#))

KaggleTestSnippet_HCA_1368_f.153v.PNG

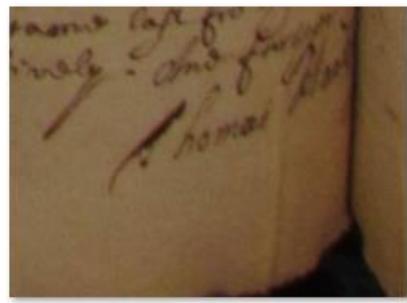

KaggleTestSnippet_HCA_1368_f.155r.PNG

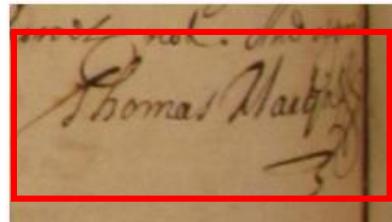

KaggleTestSnippet_HCA_1368_f.156r.PNG

KaggleTestSnippet_HCA_1368_f.158r.PNG

KaggleTestSnippet_HCA_1368_f.159v.PNG

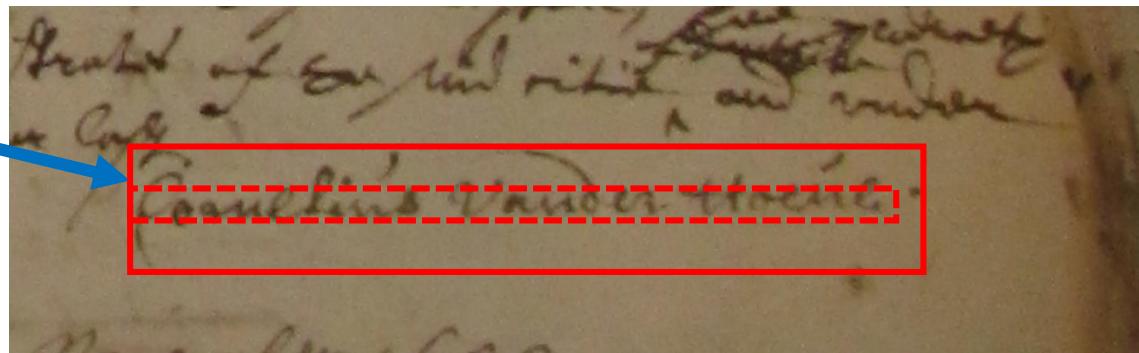

KaggleTestSnippet_HCA_1368_f.161v.PNG

Challenge Two: Detect a London based merchant, who has Dutch origin, from physical characteristics of signature, rather than spelling of name

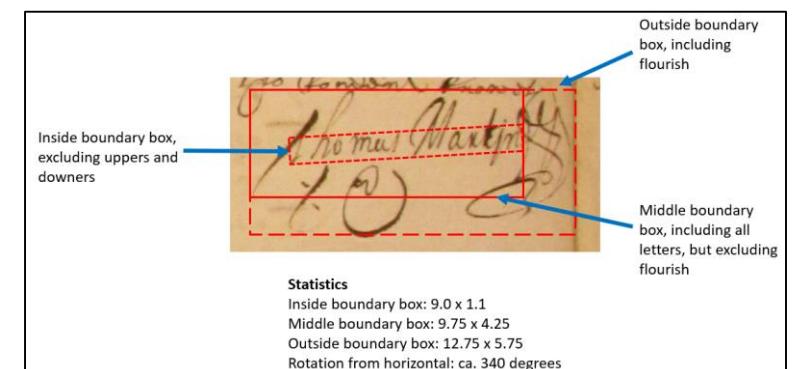

Semantic giveaways

- 3 names, not 2
- Specific names
["Cornelius"; "Vander";
"Hoene"]

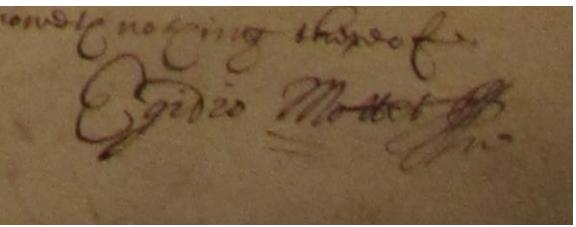

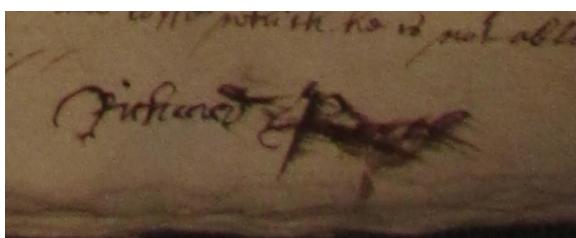

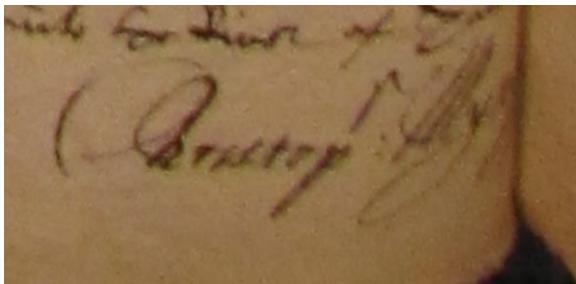

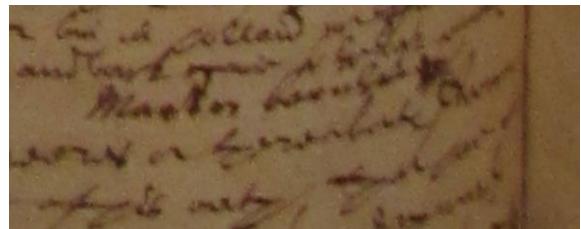

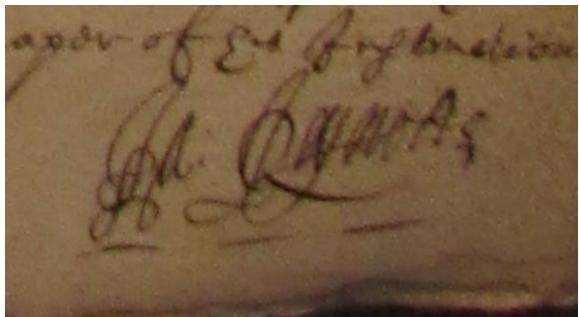

Physical giveaways

- Long, narrow signature
- No flourish
- Limited capitalisation
- Middle bounding box close to inner bounding box, with no outside bounding box

Research question - methodology: How will poor resolution imagery affect the ability of a machine to learn from an image?

Understanding How Image Quality Affects Deep Neural Networks

Samuel Dodge, Lina Karam

(Submitted on 14 Apr 2016 ([v1](#)), last revised 21 Apr 2016 (this version, v2))

Image quality is an important practical challenge that is often overlooked in the design of machine vision systems. Commonly, machine vision systems are trained and tested on high quality image datasets, yet in practical applications the input images can not be assumed to be of high quality. Recently, deep neural networks have obtained state-of-the-art performance on many machine vision tasks. In this paper we provide an evaluation of 4 state-of-the-art deep neural network models for image classification under quality distortions. We consider five types of quality distortions: blur, noise, contrast, JPEG, and JPEG2000 compression. We show that the existing networks are susceptible to these quality distortions, particularly to blur and noise. These results enable future work in developing deep neural networks that are more invariant to quality distortions.

Comments: Final version will appear in IEEE Xplore in the Proceedings of the Conference on the Quality of Multimedia Experience (QoMEX), June 6-8, 2016

Data: Notarial comments “the marke” (or more commonly “the marke of”) – in this case clearly the markes of William Hamand were added after the notary’s comments

Data: Two ffrancis Lodwick's (1637 & 1656) - Father & son?

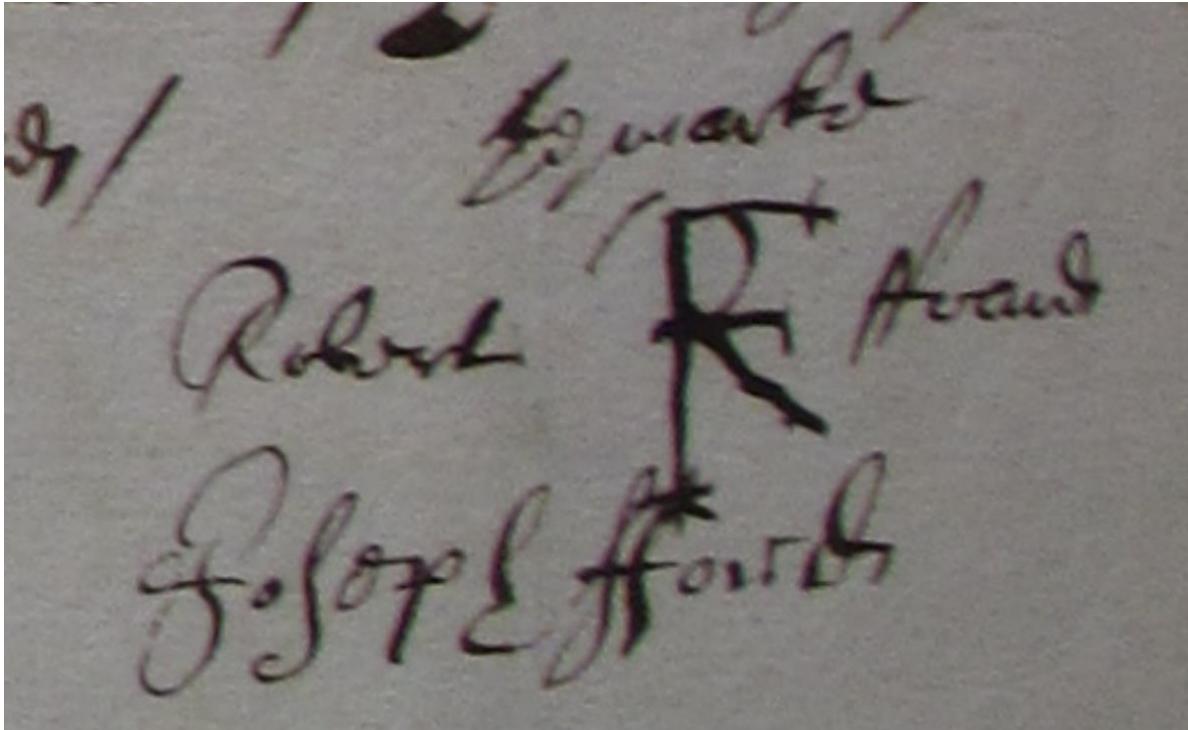

ffrancis Lodwicke of the parishe of Saint George Bottulph Lane
London merchant aged about 38 yeares [April 5th, 1637]

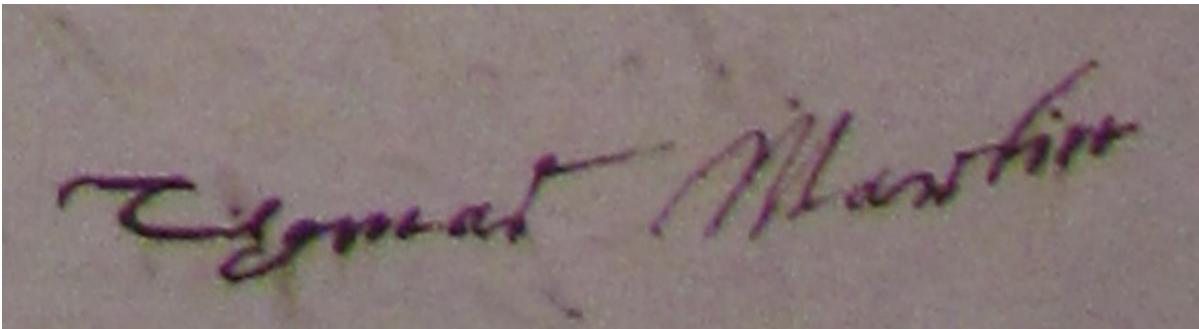

The claime of the afore said Vander Goos in the *Hare in the ffeild*... **Francis Lodwick junior** of London merchant aged 24 years...hee well knoweth the producent Marcello Vander Goos and hath so donne for theise nine yeeres last or thereabouts, this deponent for all that time (and even from his birth till about two years since that hee came to dwell in London) living in Middleborowe [Deposed on Feb 22nd 1656]

Data: Two presumably related mariners from Ipswich, one signing with initials & one with a signature

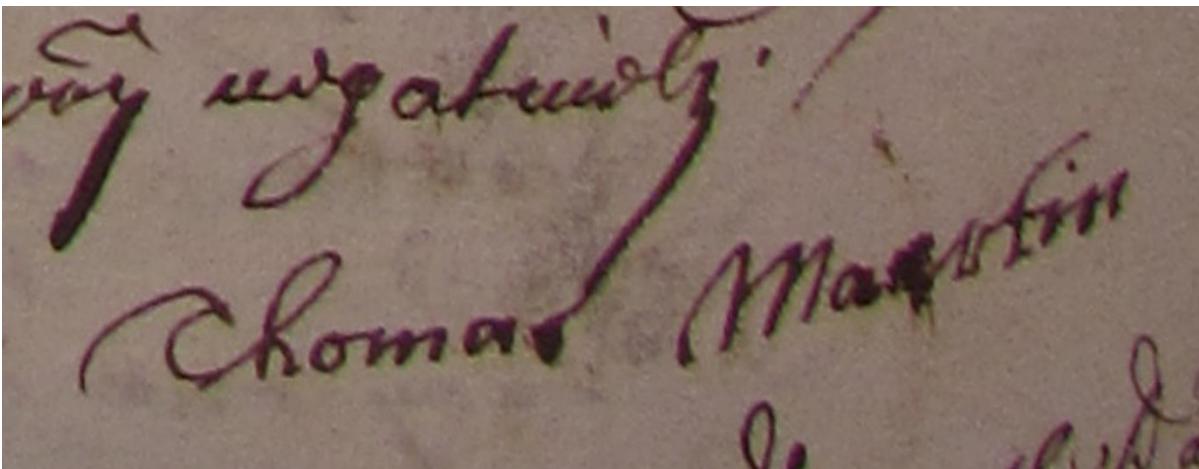

An affidavit made by **Robert ffoard** of Ipswich in the county of Suffolke mariner and **Joseph ffoard** of the same mariner touching certaine anchors and tackle belonging to a certaine hoye called the *Richard* of Ipswich cast awaye neere a place called the Shoe [December 38th 1654]

Data: Two presumably related mariners from Redriff in Middlesex, signing with distinct signatures

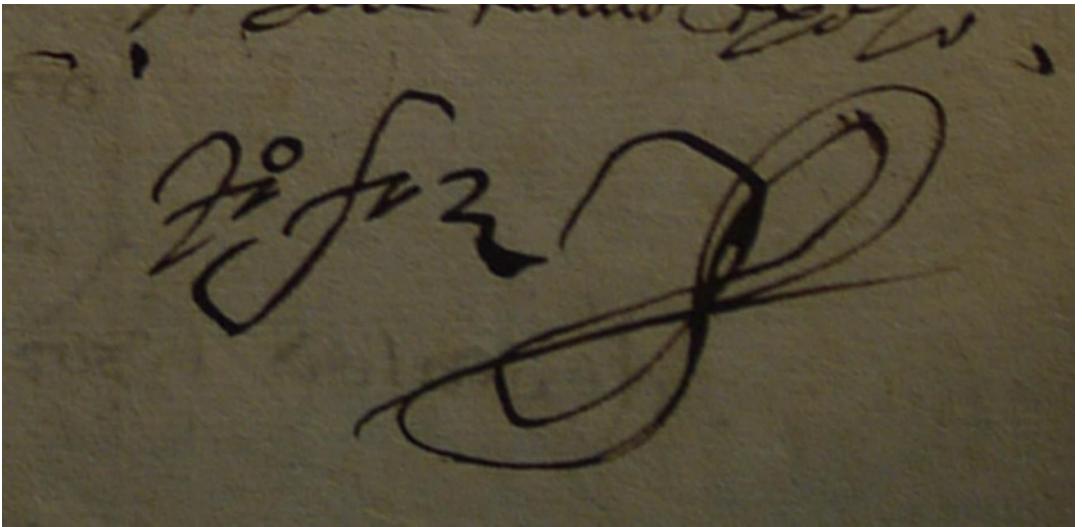

Thomas Martyn of Redriffe in the county of Middlesex maryner aged 48 yeares or thereabouts... hee was one of the Company of the shipp *Dove* whereof Walter Cable was and is master the voyage in question which was about the beginning of August last past [January 5th 1655]

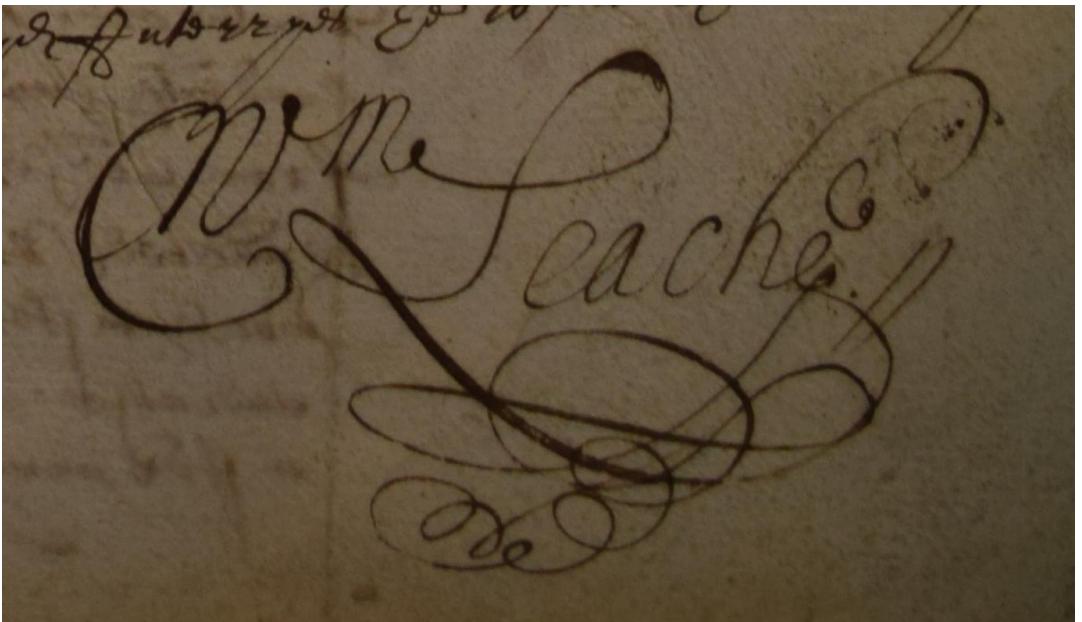

Thomas Martyn the younger of Redriffe in the county of Middlesex maryner: aged 16 yeares or thereabouts...which this deponent knoweth being one of the company of the said shipp *Dove* and being on board her all the said voyage [January 5th 1655]

Data: Flourishes of differing technical proficiency

Diego Mendez of La Palma one of the Canarie Ilands, aged 25 yeeres...hee came first aboard to serve in the ship the *Hope* interrogated in September last was a twelve moneth being then at Amsterdam whence the said shipp then departed on the voyage in question, and was spoken and agreed with by his precontest John Lopez to goe with and serve him in that voyage in the West Indias, who declared that hee desired this deponents company in that voyage, because this deponent was a Spaniard, and soe the [?XXXX] proper to colour the designe of his trade there, and did not agree with this deponent for any certaine wages, but promised to reward him according to his deserve
[Deposited on Feb 15th 1659]

William Leache of the parishe of Saint Ethelborowe London gouldsmyth aged about 36 years
[Deposited on February 6th 1637]

SUPPLEMENTARY MATERIAL

Issues

Pre-processing

- Scaling images
- Converting to grayscale
 - Some image processing & computer vision algorithms use grayscale images not colour images
 - Grayscale processing 3x faster than colour processing
- Normalising an image
 - Avoid larger feature values dominating smaller feature values [THINK ABOUT THIS]

Image processing packages

- [OpenCV](#): reads & plots an image in BGR format. Reads PNG & JPG on 0 to 255 range
- [Matplotlib](#): reads & plots an image in RGB format. Reads JPEG in 0 to 255 and PNG on 0 to 1 range

Do images need to be square for typical neural network models? Or at least have identical aspect ratios? Do we need to scale all images to a standard number of pixels for height & width? Do snippets need to be cropped to isolate the signoff? What does the mean image of a marke, an initial and a signature look like? [mean value of each pixel across all training examples]. Can also look at the standard deviation of the pixels for a group of images.

Abstract: There are many scenarios where we wish to imitate a specific author's pen-on-paper handwriting style. Rendering new text in someone's handwriting is difficult because natural handwriting is highly variable, yet follows both intentional and involuntary structure that makes a person's style self-consistent. The variability means that naive example-based texture synthesis can be conspicuously repetitive.

We propose an algorithm that renders a desired input string in an author's handwriting. An annotated sample of the author's handwriting is required; the system is flexible enough that historical documents can usually be used with only a little extra effort. Experiments show that our glyph-centric approach, with learned parameters for spacing, line thickness, and pressure, produces novel images of handwriting that look hand-made to casual observers, even when printed on paper.

1. INTRODUCTION

The worldwide adoption of digital messaging has given handwriting its commercial value. It is a personal communication channel, a means of expressing one's personality, and a means of conveying personal messages. But what can an author do if, e.g., they want to send a message that looks like it was written by another author? Can they affect the style and change the legibility of their messages? Handwriting synthesis is a field that has been around since at least 2011 [Reinhard et al. 2011] and represents two families of solutions that may help, but look obviously synthetic. One problem algorithm is a new algorithm that generates handwriting that looks like it was written by another author. Another problem is that it is not always clear what the original pen-on-paper handwriting style is.

As a first step, we ask the user to end-user annotates an author's historical handwriting sample and follows a simple principle called annotation pipeline.

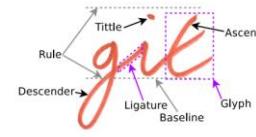

Fig. 2. Glossary of the key parts of handwritten text.

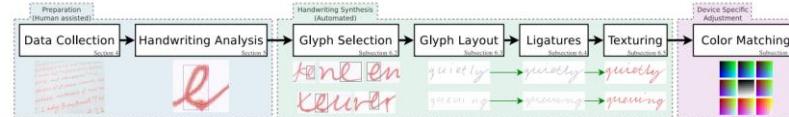

Fig. 4. System diagram showing our processing pipeline, with representative images for each stage. After samples are collected and analyzed, the rendering system selects a glyph to represent each character, e.g. "e" as shown here. If there are many choices, it must choose one that fits the surrounding text. The glyphs are then positioned on the page, and ligatures added if the author uses joined up writing. Two example words are given for these three stages, "quietly" and "queuing." Finally, the texture is transferred from the original input to the vector output and, if being printed, color correction is applied.

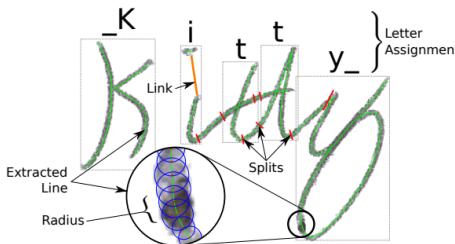

Fig. 5. Visualization of the output of the tagging process. The line is vectorized, and has radius calculated at every pixel along it. Not shown is the ink density, which is also calculated for every pixel as the average within the circle defined by the radius. The line forms a graph, to which splits are added to delineate each letter and ligature. If a letter has multiple parts then a link combines them. Finally, the parts are tagged with the relevant letter/digit/punctuation and underscores used to indicate the starts and ends of words. Ligatures are left implicit, as any path that connects two tagged glyphs.

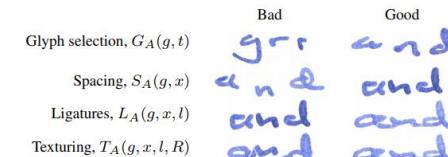

Fig. 8. Synthesis of the word "and", demonstrating what each component of the cost function does. All steps are dependent on the author's specific style, e.g. here we show that having ligatures is preferred, but if the author has print handwriting then the inclusion of ligatures would be wrong. Note that the last two good exemplars are different, as visible between the "a" and "n."

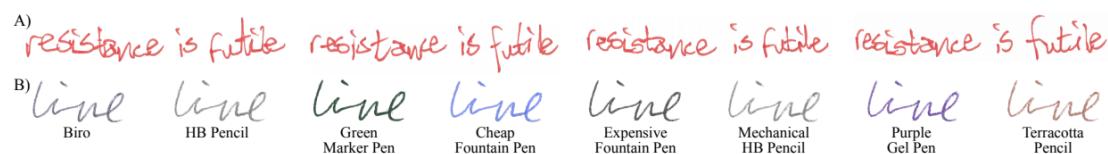

Fig. 10. A) Same sentence generated multiple times, to demonstrate output variability. The first instance is the maximum likelihood output, which would otherwise be returned every time. B) Line replacement, where one writing implement is replaced with another. First on the left is the source with the original texture. While the replacement is visually coherent, the geometric path and density variability of the previous pen is kept, which is sometimes unrealistic.

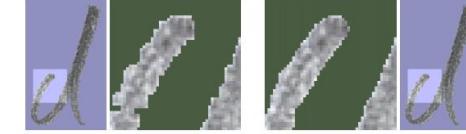

Fig. 6. Segmentation on the left shows the graph cuts result without line aware smoothing. The right side shows the improvement of smoothing. Writing implement is a pencil.

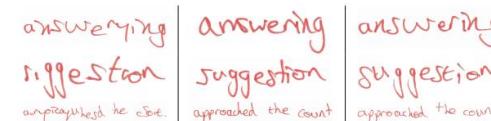

Fig. 7. Comparison of automatic only (left column) with human assisted tagging (right column). Ground truth, a sample of the authors actual writing, is in the central column.

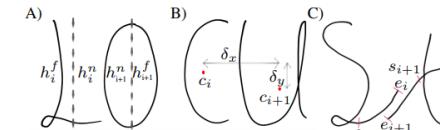

Fig. 11. A) The near-far labeling scheme for halves of a glyph, as used for the distance learning feature. B) Two glyphs, "c" and "u", with their centers (c_i and c_{i+1}) and the horizontal (δ_x) and vertical (δ_y) offset between them marked. C) Two glyphs, "s" and "t", with attached ligatures delineated by the regions within the red marks. The ligature end points are labeled with the variables used for their coordinates.

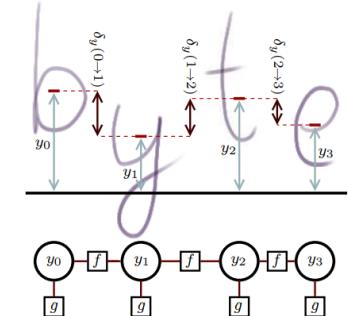

Fig. 12. Factor graph of Kalman smoothing, used to ensure the synthesized text flows. The y_i random variables (circles) indicate how far off the baseline to position each glyph. Factors (squares) indicate probabilities over the random variables to which they are connected. Kalman smoothing finds the most probable assignment of y_i values. There are two types of factor. g factors indicate that the glyphs are probably on the baseline, as a Gaussian distribution where the mean is the displacement of the glyph in the training data, h_i . This factor is $y_i \sim \mathcal{N}(h_i, 1)$. f factors indicate the displacement between adjacent glyphs, δ_y , as given in (7). When ligatures exist they provide this term, but when omitted (e.g. print handwriting) it is provided by a regression forest.

Understanding How Image Quality Affects Deep Neural Networks

Samuel Dodge, Lina Karam

(Submitted on 14 Apr 2016 (v1), last revised 21 Apr 2016 (this version, v2))

Image quality is an important practical challenge that is often overlooked in the design of machine vision systems. Commonly, machine vision systems are trained and tested on high quality image datasets, yet in practical applications the input images can not be assumed to be of high quality. Recently, deep neural networks have obtained state-of-the-art performance on many machine vision tasks. In this paper we provide an evaluation of 4 state-of-the-art deep neural network models for image classification under quality distortions. We consider five types of quality distortions: blur, noise, contrast, JPEG, and JPEG2000 compression. We show that the existing networks are susceptible to these quality distortions, particularly to blur and noise. These results enable future work in developing deep neural networks that are more invariant to quality distortions.

Comments: Final version will appear in IEEE Xplore in the Proceedings of the Conference on the Quality of Multimedia Experience (QoMEX), June 6-8, 2016

Labeled Faces in the Wild: A Survey.

In *Advances in Face Detection and Facial Image Analysis*, edited by Michal Kawulok, M. Emre Celebi, and Bogdan Smolka, Springer, pages 189-248, 2016.

[[Springer Page](#)] [[Draft pdf](#)]

NEW RESULTS PAGE:

WE HAVE RECENTLY UPDATED AND CHANGED THE FORMAT AND CONTENT OF OUR [RESULTS PAGE](#). PLEASE REFER TO THE [NEW TECHNICAL REPORT](#) FOR DETAILS OF THE CHANGES.

Welcome to Labeled Faces in the Wild, a database of face photographs designed for studying the problem of unconstrained face recognition. The data set contains more than 13,000 images of faces collected from the web. Each face has been labeled with the name of the person pictured. 1680 of the people pictured have two or more distinct photos in the data set. The only constraint on these faces is that they were detected by the Viola-Jones face detector. More details can be found in the technical report below.

There are now four different sets of LFW images including the original and three different types of "aligned" images. The aligned images include "funneled images" (ICCV 2007), LFW-a, which uses an unpublished method of alignment, and "deep funneled" images (NIPS 2012). Among these, LFW-a and the deep funneled images produce superior results for most face verification algorithms over the original images and over the funneled images (ICCV 2007).

Labeled Faces in the Wild: A Survey

Erik Learned-Miller, Gary Huang, Aruni RoyChowdhury, Haoxiang Li, Gang Hua

Abstract In 2007, Labeled Faces in the Wild was released in an effort to spur research in face recognition, specifically for the problem of face verification with unconstrained images. Since that time, more than 50 papers have been published that improve upon this benchmark in some respect. A remarkably wide variety of innovative methods have been developed to overcome the challenges presented in this database. As performance on some aspects of the benchmark approaches 100% accuracy, it seems appropriate to review this progress, derive what general principles we can from these works, and identify key future challenges in face recognition. In this survey, we review the contributions to LFW for which the authors have provided results to the curators (results found on the LFW results web page). We also review the cross cutting topic of alignment and how it is used in various methods. We end with a brief discussion of recent databases designed to challenge the next generation of face recognition algorithms.

Abstract

Determining handwriting authorship of a written text has practical significance in the realm of forensics, signature verification, and literary history. While there have been studies in signature verification and handwriting classification, a vast literature review reveals that very little work has been done in handwriting verification. Recent advances in convolutional architectures, particularly those involving facial verification, suggest that the task can be tackled effectively. In this study, we build a Siamese convolutional neural network to determine whether two pieces of handwriting are written by the same author. We examine questions such as whether long pieces of handwriting must be present to achieve good results, how many samples are needed, what features are important, and how different architectures perform on this task. We explore different convolutional architectures like VGG, GoogLeNet and ResNet, to determine which architecture produces the best encoding of each sample. We note that our best performing single model, TinyResNet, achieves a 92.08% accuracy on the held out test set.

1. Introduction

Determining the authorship of a written text has practical significance in the realm of forensics, signature verification, and literary history [3]. In manuscript analysis, for instance, historians frequently ask questions regarding the number of authors for a text, whether an anonymous work can be confidently attributed to a historical figure, and what time period a text might be from. These kinds of analyses are all based upon comparisons between different writing samples [1]. Techniques in the field have remained largely subjective, however, making the transition to automatic tools difficult.

In addition, handwriting analysis is an established area of study in forensics, but there has not yet been any formal experiments measuring the accuracy of such analysis. As a result, the field is surrounded by much skepticism because of how subjective the process is (compared to, say, DNA testing) [5]. In addition, forensic handwriting analysis is time-intensive and requires two years of training for a person to obtain proper qualifications. The primary objective of this project is to develop an automatic, high-accuracy system which can determine if any two writing samples are written by the same person. In addition, our system should be able to handle authors it has never encountered before.

2. Background and Related Work

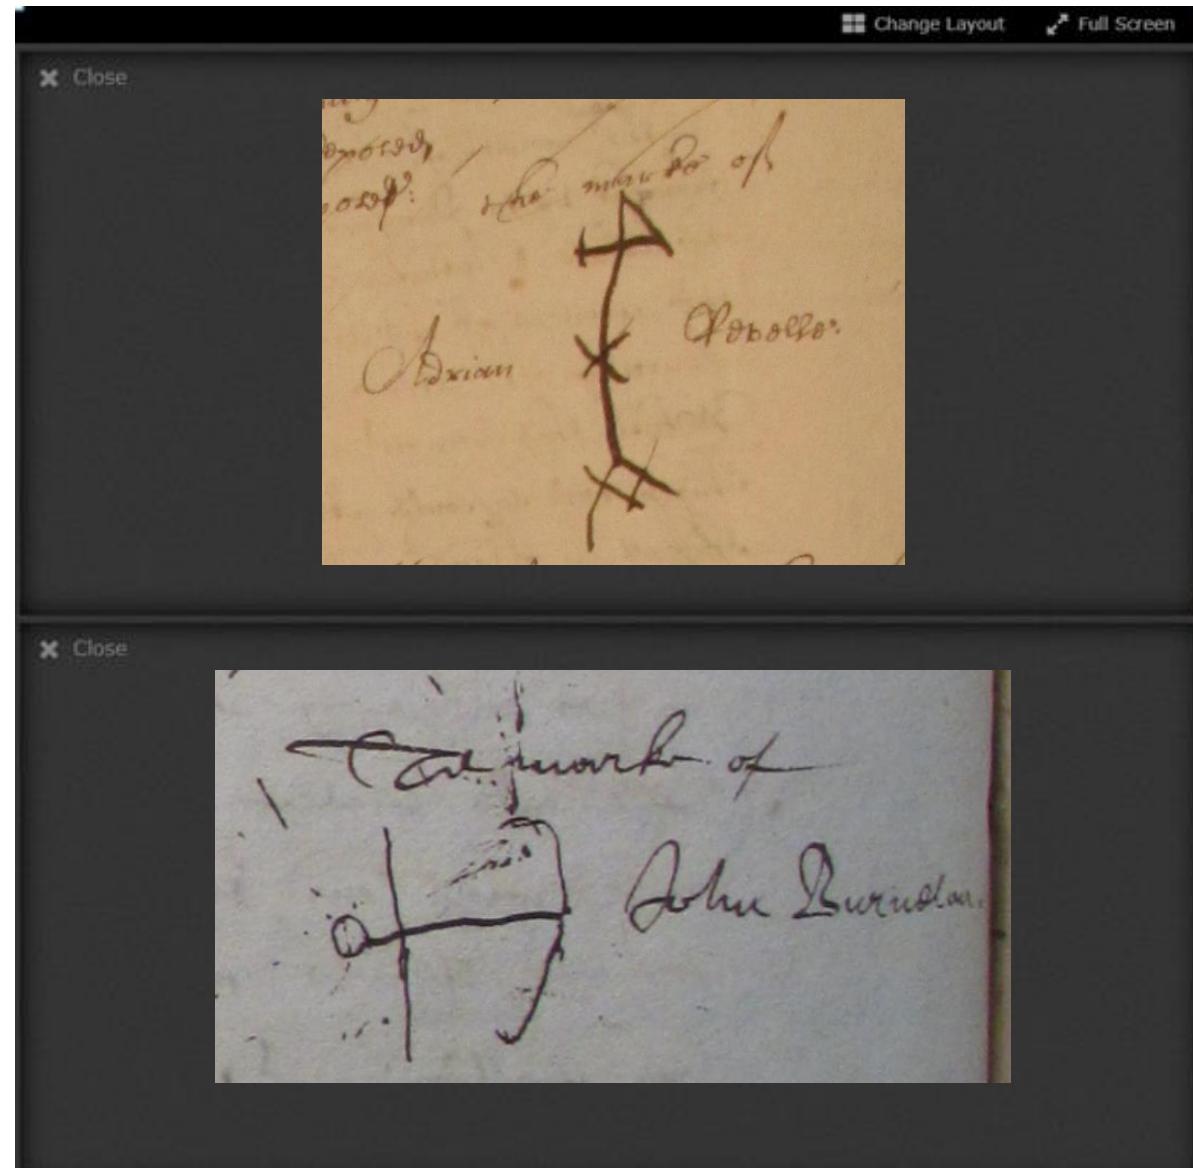

Our objective fits well with the Siamese CNN neural network architecture, which was first developed in 1993 to tackle the signature verification problem. [3] This type of architecture takes in two inputs and outputs a distance metric for the inputs. Bromley et al. was able to detect 95% of genuine signatures using this architecture. However, note that the signature verification problem expects a pair of inputs to be very similar to each other to be considered a match. This setup would not be effective for the problem we are trying to tackle, because our system should be agnostic to the actual text in a writing sample.

Other researchers have focused more closely on the authorship identification problem. A study in 2015 by Xing et al. reported an accuracy of 97% in classifying English writing samples for 657 authors. [11] They used the same dataset we will be using in this paper, the IAM Handwriting Database, and a 4-layer CNN. This study gave us confidence that we can achieve high accuracies on authorship problems using the IAM dataset. In a very recent research study from 2016, Yang et al. was able to achieve a 95% accuracy in classifying the authors for Chinese text samples,

The screenshot shows a browser extension for the David Rumsey Map Collection. At the top, it says "David Rumsey Map Collection - MapTab" with a "ADD TO CHROME" button. Below that is a map of the United States with a red arrow pointing from the West Coast to the East Coast, labeled "7:44 AM". The date is "Tuesday, September 29, 2015". To the right of the map is a sidebar with the following text:
